3DM-GX3-45 API

API Introduction

The 3DM-GX3-45 programming interface is comprised of a compact set of setup and control commands and a very flexible user-configurable data output format. The commands and data are divided into 4 command sets and 3 data sets corresponding to the internal architecture of the device. The four command sets consist of a set of "Base" commands (a set that is common across many types of devices), a set of unified "3DM" (3D Motion) commands that are specific to the MicroStrain inertial product line, a set of "NAV" (Navigation) commands that are specific to MicroStrain navigation devices, and a set of "System" commands that are specific to sensor systems comprised of more than one internal sensor block. The three data sets represent the three types of data that the 3DM-GX3-45 is capable of producing: "AHRS" (Attitude and Heading Reference System) data, "GPS" (Global Positioning Sensor) data, and "NAV" (Navigation) data.

Base commands Ping, Idle, Resume, Get ID Strings, etc.
3DM commands Poll AHRS Data, Poll GPS Data, etc.

NAV commands Reset Filter, Sensor to Vehicle Frame Transformation, etc.

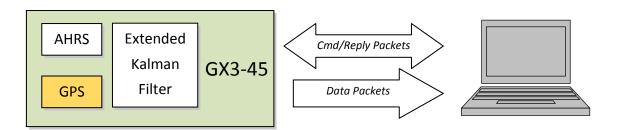

System commands Switch Communications Mode, etc.

AHRS data Acceleration Vector, Gyro Vector, Euler Angles, etc.

GPS data Latitude, Longitude, UTC, Satellites in view, etc.

NAV data Position, Velocity, Attitude Estimates, etc.

The protocol is packet based. All commands, replies, and data are sent and received as fields in a message packet. The packets have a descriptor type field based on their contents, so it is easy to identify if a packet contains commands, replies, AHRS data, GPS data, or NAV data.

The 3DM-GX3-45 has an advanced mode switch that allows the device to switch into direct "AHRS" or "GPS" mode. In those modes, the device responds to the native protocols of the 3DM-GX3-25 AHRS or the u-blox5 GPS devices which are imbedded in the 3DM-GX3-45. These modes can be used to access advanced or specialized features of these devices (see the <u>Advanced Programming</u> section).

Command and Data Summary

Below is a summary of the commands and data available in the programming interface. Commands and data are denoted by two values. The first value denotes the "descriptor set" that the command or data belongs to (Base command, 3DM command, AHRS data, or GPS data) and the second value denotes the unique command or data "descriptor" in that set.

Commands

Base Command Set (0x01)

•	Ping	(0x01, 0x01)
•	Set To Idle	(0x01, 0x02)
•	Get Device Information	(0x01, 0x03)
•	Get Device Descriptor Sets	(0x01, 0x04)
•	Device Built-In Test (BIT)	(0x01, 0x05)
•	<u>Resume</u>	(0x01, 0x06)
•	Device Reset	(0x01, 0x7E)

3DM Command Set (0x0C)

•	Poll AHRS Data	(0x0C, 0x01)
•	Poll GPS Data	(0x0C, 0x02)
•	Poll NAV Data	(0x0C, 0x03)
•	Get AHRS Data Rate Base	(0x0C, 0x06)
•	Get GPS Data Rate Base	(0x0C, 0x07)
•	Get NAV Data Rate Base	(0x0C, 0x0B)
•	AHRS Message Format	(0x0C, 0x08)
•	GPS Message Format	(0x0C, 0x09)
•	NAV Message Format	(0x0C, 0x0A)
•	Enable/Disable Device Continuous Data Stream	(0x0C, 0x11)
•	Device Startup Settings	(0x0C, 0x30)
•	AHRS Signal Conditioning Settings	(0x0C, 0x35)
•	Change UART BAUD rate	(0x0C, 0x40)
•	<u>Device Status</u> *	(0x0C, 0x64)

Basic Programming

The 3DM-GX3-45 is designed to stream NAV, AHRS, and GPS data packets over a common interface as efficiently as possible. To this end, programming the device consists of a configuration stage where the data messages and data rates are configured. The configuration stage is followed by a data streaming stage where the program starts the incoming data packet stream.

In this section there is an overview of the packet, an overview of command and reply packets, an overview of how an incoming data packet is constructed, and then an example setup command sequence that can be used directly with the 3DM-GX3-45 either through a COM utility or as a template for software development.

MIP Packet Overview

This is an overview of the 3DM-GX3-45 packet structure. The packet structure used is the MicroStrain "MIP" packet. A reference to the general packet structure is presented in the MIP Packet Reference section. An overview of the packet is presented here.

The MIP packet "wrapper" consists of a four byte header and two byte checksum footer:

		Header		Packet Payload			Checksum		
SYNC1 "u"	SYNC2 "e"	Descriptor Set byte	Payload Length byte	Field Length byte	o ,				
0x75	0x65	0x80	0x0E	0x0E 0x0B 0x3E 7A 63 A0 0xBB 8E 3B 29 0x7F E5 BF 7F			0x83	0xE1

Touped into different sets. ket as an AHRS data perform the AHRS data			
						s. These are the same for identify the start of the			
				2 byte Fletche	r checksum of all th	ne bytes in the packet.			

The packet payload section contains one or more fields. Fields have a length byte, descriptor byte, and data. The diagram below shows a packet payload with a single field.

	ŀ	Header		Packet Payload			Checksum			
SYNC1 "u"	SYNC2 "e"	Descriptor Set byte	Payload Length byte	Field Length byte	·					
0x75	0x65	0x80	0x0E	0x0E	0x06	0x3E 7A 63 A0 0xBB 8E 3B 29 0x7F E5 BF 7F	0x86	80x0

0x75	0x65	0x80	0x1C	0x0E	0x05	0x3E 7A 63 A0 0xBB 8E 3B 29 0x7F E5 BF 7F	0x0E	0x06	0x3E 7A 63 A0 0xBB 8E 3B 29 0x7F E5 BF 7F	0xB1	0x1E

Command Overview

The basic command sequence begins with the host sending a command to the device. A command packet contains a field with the command value and any command arguments.

The device responds by sending a reply packet. The reply contains at minimum an ACK/NACK field. If any additional data is included in a reply, it appears as a second field in the packet.

Example "Ping" Command Packet:

Below is an example of a "Ping" command packet from the Base command set. A "Ping" command has no arguments. Its function is to determine if a device is present and responsive:

	I	Header			Packet Pay	rload	Checksum		
SYNC1 "u"	SYNC2 "e"	Descriptor Set byte	Payload Length byte	Field Length byte	Field Descriptor byte	Field Data	MSB	LSB	
0x75	0x65	0x01	0x02	0x02	0xE0	0xC6			

Copy-Paste version: "7565 0102 0201 E0C6"

The packet header has the "ue" starting sync bytes characteristic of all <u>MIP packets</u>. The descriptor set byte (0x01) identifies the data as being from the Base command set. The length of the payload portion is 2 bytes. The payload portion of the packet consists of one field. The field starts with the length of the field which is followed by the descriptor byte (0x01) of the field. The field descriptor value *is* the command value. Here the descriptor identifies the command as the "Ping" command from the Base command descriptor set. There are no parameters associated with the ping command, so the field data is empty. The checksum is a two byte <u>Fletcher checksum</u> (see the <u>MIP Packet Reference</u> for instructions on how to compute a Fletcher two byte checksum).

Example "Ping" Reply Packet:

The "Ping" command will generate a reply packet from the device. The reply packet will contain an ACK/NACK field. The ACK/NACK field contains an "echo" of the command byte plus an error code. An error code of 0 is an "ACK" and a non-zero error code is a "NACK":

	ŀ	Header			Packet Payload					
SYNC1 "u"	SYNC2 "e"	Descriptor Set byte	Payload Length byte	Field Length byte	, ,					
0x75	0x65	0x01	0x04	0x04	0xF1	Command echo: 0x01 Error code: 0x00	0xD5	0x6A		

Copy-Paste version: "7565 0104 04F1 0100 D56A"

The packet header has the "ue" starting sync bytes characteristic of all MIP packets. The descriptor set byte (0x01) identifies the payload fields as being from the Base command set. The length of the payload portion is 4 bytes. The payload portion of the packet consists of one field. The field starts with the length of the field which is followed by the descriptor byte (0xF1) of the field. The field descriptor byte identifies the reply as the "ACK/NACK" from the Base command descriptor set. The field data consists of an "echo" of the original command (0x01) followed by the error code for the command (0x00). In this case the error is zero, so the field

represents an "ACK". Some examples of non-zero error codes that might be sent are "timeout", "not implemented", and "invalid parameter in command". The checksum is a two byte <u>Fletcher checksum</u> (see the <u>MIP Packet Reference</u> for instructions on how to compute a Fletcher two byte checksum).

The ACK/NACK descriptor value (0xF1) is the same in all descriptor sets. The value belongs to a set of reserved global descriptor values.

The reply packet may have additional fields that contain information in reply to the command. For example, requesting <u>Device Status</u> will result in a reply packet that contains two fields in the packet payload: an ACK/NACK field and a device status information field.

Data Overview

Data packets are generated by the device. When the device is powered up, it may be configured to immediately stream data packets out to the host or it may be "idle" and waiting for a command to either start continuous data or to get data by "polling" (one data packet per request). Either way, the data packet is generated by the device in the same way.

Example Data Packet:

Below is an example of a MIP data packet which has one field that contains the scaled accelerometer vector.

	ŀ	Header			Packet Payload				
SYNC1 "u"	SYNC2 "e"	Descriptor Set byte	Payload Length byte	Field Length byte	Field Descriptor byte	Field Data: Accel vector (12 bytes, 3 float – X, Y, Z)	MSB	LSB	
0x75	0x65	0x80	0x0E	0x0E	0x04	0x3E 7A 63 A0 0xBB 8E 3B 29 0x7F E5 BF 7F	0x92	0xC0	

Copy-Paste version: "7565 800E 0E03 3E7A 63A0 BB8E 3B29 7FE5 BF7F 83E1"

The packet header has the "ue" starting sync bytes characteristic of all MIP packets. The descriptor set byte (0x80) identifies the payload field as being from the AHRS data set. The length of the packet payload portion is 14 bytes (0x0E). The payload portion of the packet starts with the length of the field. The field descriptor byte (0x01) identifies the field data as the scaled accelerometer vector from the AHRS data descriptor set. The field data itself is three single precision floating point values of 4 bytes each (total of 12 bytes) representing the X, Y, and Z axis values of the vector. The checksum is a two byte <u>Fletcher checksum</u> (see the <u>MIP Packet Reference</u> for instructions on how to compute a Fletcher two byte checksum).

The format of the field data is fully and unambiguously specified by the descriptor. In this example, the field descriptor (0x04) specifies that the field data holds an array of three single precision IEEE-754 floating point numbers in big-endian byte order and that the values represent units of "g's" and the order of the values is X, Y, Z vector order. Any other specification would require a different descriptor (see the <u>Data Reference</u> section of this manual).

Each packet can contain any combination of data quantities from the same data descriptor set (any combination of GPS data OR any combination of AHRS data OR and combination of NAV data—you cannot combine GPS data, AHRS data, and NAV data in the same packet).

Data polling commands generate two individual reply packets: An ACK/NACK packet and a data packet. Enable/Disable continuous data commands generate an ACK/NACK packet followed by the continuous stream of data packets.

The AHR, GPS, and NAV data packets can be set up so that each data quantity is sent at a different rate. For example, you can setup continuous data to send the accelerometer vector at 100Hz and the magnetometer vector at 5Hz. This means that packets will be sent at 100Hz and each one will have the accelerometer vector but only every 20th packet will have the magnetometer vector. This helps reduce bandwidth and buffering requirements. An example of this is given in the AHRS Message Format command.

Example Setup Sequence

Setup involves a series of command/reply pairs. The example below demonstrates actual setup sequences that you can send directly to the 3DM-GX3-45 either programmatically or by using a COM utility. In most cases only minor alterations will be needed to adapt these examples for your application.

Continuous Data Example Command Sequence

Most applications will operate with the 3DM-GX3-45 sending a continuous data stream. In the following example, the AHRS data format is set, followed by the NAV data format. GPS data will not be included as we will not be cross-checking against the navigation solution. To reduce the amount of streaming data, if present during the configuration, the device is placed into the idle state while performing the device initialization; when configuration is complete, the required data streams are enabled and the "Resume" command is issued to bring the device out of idle mode. These are not required steps, but are shown here for reference. Finally, the configuration is saved so that it will be loaded on subsequent power-ups, eliminating the need to perform the configuration again.

Step 1: Put the Device in Idle Mode (Disabling the AHRS, GPS, and NAV data-streams)

Send the "Set To Idle" command to put the device in the idle state (reply is ACK/NACK). This is not required but reduces the parsing burden during initialization and makes visual confirmation of the commands easier:

	MIP Pack	et Header			Comman	d/Reply Fie	elds	Checksum	
Step 1	Sync1	Sync2	Desc Set	Payload Length	Field Length	Cmd Desc.	Field Data	MSB	LSB
Command Set to Idle	0x75	0x65	0x01	0x02	0x02	0x02	N/A	0xE1	0xC7
Reply ACK/NACK	0x75	0x65	0x01	0x04	0x04	0xF1	Cmd echo: 0x02 Error code: 0x00	0xD6	0x6C

Copy-Paste version of the command: "7565 0102 0202 E1C7"

Step 2: Configure the AHRS data-stream format

Send a "<u>Set AHRS Message Format</u>" command (reply is ACK/NACK). This example requests scaled gyro, scaled accelerometer, and GPS Correlation Timestamp information at 100 Hz (100Hz base rate, with a rate decimation of 1 on the GX3-45 = 100 Hz.) This will result in a single AHRS data packet sent at 100 Hz containing the scaled gyro field followed by the scaled accelerometer field followed by the AHRS GPS Timestamp. This is a very typical configuration for a base level of inertial data. If different rates were requested, then each packet would only contain the data quantities that fall in the same decimation frame (see the <u>Multiple Rate Data</u> section). If the stream was not disabled in the previous step, the AHRS data would begin stream immediately.

Please note, this command will not append the requested descriptors to the current AHRS data-stream configuration, it will overwrite it completely:

	MIP Pack	et Header			Comman	d/Reply Fie	elds	Checksum	
Step 2	Sync1	Sync2	Desc Set	Payload Length	Field Length	Cmd Desc.	Field Data	MSB	LSB
Command New AHRS Message Format	0x75	0x65	0x0C	0x0D	0x0D	0x08	Function: 0x01 Desc count: 0x03 1 st Descriptor: 0x04 Rate Dec: 0x0001 2 nd Descriptor: 0x05 Rate Dec: 0x0001 3 rd Descriptor: 0x12 Rate Dec: 0x0001	0x2A	0x35
Reply ACK/NACK	0x75	0x65	0x0C	0x04	0x04	0xF1	Cmd echo: 0x08 Error code: 0x00	0xE7	0хВА

Copy-Paste version of the command: "7565 OCOD 0D08 0103 0400 0105 0001 1200 012A 35"

Step 3: Configure the NAV data-stream format

The following configuration command requests the Estimated LLH Position, Estimated NED Velocity, Estimated Orientation in Quaternion form, and Filter Status at 20 Hz (100Hz base rate, with a rate decimation of 5 = 20 Hz.) This will result in a single NAV packet sent at 20 Hz containing the requested fields in the requested order. If different rates were requested, the each packet would only contain the data quantities that fall in the same data rate frame (see the Multiple Rate Data section). If the stream was not disabled in the previous step, the NAV data would begin stream immediately.

Please note, this command will not append the requested descriptors to the current NAV data-stream configuration, it will overwrite it completely.

	MIP Pack	et Header			Comman	d/Reply Fie	elds	Checksum	
Step 3	Sync1	Sync2	Desc Set	Payload Length	Field Length	Cmd Desc.	Field Data	MSB	LSB
Command New NAV Message Format	0x75	0х65	0x0C	0x10	0x10	0x0A	Function: 0x01 Desc Count: 0x04 Est. Pos desc: 0x01 Rate dec: 0x0005 Est. Vel desc: 0x02 Rate dec: 0x0005 Est. Quat desc: 0x03 Rate dec: 0x0005 Filter Status desc: 0x10 Rate dec: 0x0005	0x3F	0x31
Reply ACK/NACK	0x75	0x65	0x0C	0x04	0x04	0xF1	Cmd echo: 0x0A Error code: 0x00	0xE9	ОхВЕ

Copy-Paste version of the command: "7565 0C10 100A 0104 0100 0502 0005 0300 0510 0005 3F31"

Step 4: Save the AHRS and NAV MIP Message format

To save the AHRS and NAV MIP Message format, use the "Save" function selector (0x03) in the AHRS and NAV Message Format commands. Below we've combined the two commands as two fields in the same packet. Notice that the two reply ACKs comes in one packet also. Alternatively, they could be sent as separate packets.

	MIP Pack	et Header			Comman	d/Reply Fie	elds	Checksu	m
Step 4	Sync1	Sync2	Desc Set	Payload Length	Field Length	Cmd Desc.	Field Data	MSB	LSB
Command field 1 Save Current AHRS Message Format	0x75	0x65	0x0C	0x08	0x04	0x08	Function: 0x03 Desc count: 0x00		
Command field 2 Save Current NAV Message Format					0x04	0x0A	Function: 0x03 Desc count: 0x00	0x0E	0x31
Reply field 1 ACK/NACK	0x75	0x65	0x0C	0x08	0x04	0xF1	Cmd echo: 0x08 Error code: 0x00		
Reply field 2 ACK/NACK					0x04	0xF1	Cmd echo: 0x0A Error code: 0x00	0xEA	0x71

Copy-Paste version of the command: "7565 0C08 0408 0300 040A 0300 0E31"

Step 5: Enable the AHRS and NAV data-streams

Send an "Enable/Disable Continuous Stream" command to enable the AHRS and NAV continuous streams (reply is ACK). These streams may have already been enabled by default, this step is to confirm they are enabled. These streams will begin streaming data immediately.

	MIP Pack	MIP Packet Header				d/Reply Fie	elds	Checksum	
Step 5	Sync1	Sync2	Desc Set	Payload Length	Field Length	Cmd Desc.	Field Data	MSB	LSB
Command field 1 Enable Continuous AHRS Message	0x75	0x65	0x0C	0х0А	0x05	0x11	Fctn: 0x01 AHRS: 0x01 ON: 0x01		
Command field 2 Enable Continuous NAV Message					0x05	0x11	Fctn: 0x01 NAV: 0x03 ON: 0x01	0x24	ОхСС

Reply field 1 ACK/NACK	0x75	0x65	0x0C	0x08	0x04	0xF1	Cmd echo: 0x11 Error code: 0x00		
Reply field 2 ACK/NACK					0x04	0xF1	Cmd echo: 0x11 Error code: 0x00	0xFA	0xB5

Copy-Paste version of the command: "7565 0C0A 0511 0101 0105 1101 0301 24 CC"

Step 6 (Optional): Resume the Device

Send the "Resume" command to re-enable transmission of enabled data streams (reply is ACK/NACK).

Step 6	MIP Pack	et Header			Comman	d/Reply Fie	elds	Checksum	
	Sync1	Sync2	Desc Set	Payload Length	Field Length	Cmd Desc.	Field Data	MSB	LSB
Command Resume	0x75	0x65	0x01	0x02	0x02	0x06	N/A	0xE5	0хСВ
Reply ACK/NACK	0x75	0x65	0x01	0x04	0x04	0xF1	Cmd echo: 0x06 Error code: 0x00	0xDA	0x74

Copy-Paste version of the command: "7565 0102 0206 E5CB"

Step 7: Initialize the Filter

At this point in the set-up, the GX3-45 is streaming data, but the Kalman Filter is not yet initialized. For a successful initialization to occur, the GPS must have a fix and the initial orientation must be known. The orientation may be initialized in 4 different ways: Setting all of the attitude elements manually, setting only the heading and allowing the device to determine pitch and roll, using the internal AHRS solution (which requires the magnetometers) to provide the initial orientation, or via auto-initialization, which uses the heading update to initialize. In this example, we will assume the magnetometers are available and use the AHRS solution to initialize the Kalman Filter. Once the attitude is initialized and the GPS fix becomes valid, the Kalman Filter estimation will propagate:

Step 7	MIP Pack	et Header			Comman	d/Reply Fie	elds	Checksum	
	Sync1	Sync2	Desc Set	Payload Length	Field Length	Cmd Desc.	Field Data	MSB	LSB
Command Disable Continuous	0x75	0x65	0x0D	0x06	0x06	0x04	Declination: 0.0 deg 0x00000000	0xF7	0xE9
Reply ACK/NACK	0x75	0x65	0x0D	0x04	0x04	0xF1	Cmd echo: 0x04 Error code: 0x00	0xE4	0xB8

Copy-Paste version of the command: "7565 0D06 0604 0000 0000 F7E9"

Polling Data Example Sequence

Polling for data is less efficient than processing a continuous data stream, but may be more appropriate for certain applications. The main difference from the continuous data example is the inclusion of the Poll data commands in the data loop:

Step 1: Put the Device in Idle Mode (Disabling the AHRS, GPS, and NAV data-streams)

Same as continuous streaming. See <u>above</u>.

Step 2: Configure the AHRS data-stream format

Same as continuous streaming. See above.

Step 3: Configure the NAV data-stream format

Same as continuous streaming. See above.

Step 4: Save the AHRS and NAV MIP Message format

Same as continuous streaming. See above.

Step 5: Resume the Device

Same as continuous streaming step 6. See <u>above</u>.

Step 6: Initialize the Filter

Same as continuous streaming step 7. See above.

Step 7: Send individual data polling commands

Send individual <u>Poll AHRS Data</u> and <u>Poll NAV Data</u> commands in your data collection loop. After the ACK/NACK is sent by the device, a single data packet will be sent according to the settings in the previous steps. Note that the ACK/NACK has the same descriptor set value as the command, but the data packet has the descriptor set value for the type of data (AHRS or NAV):

	MIP Pack	et Header			Comman	d/Reply Fie	lds	Checksum	
Step 5	Sync1	Sync2	Desc Set	Payload Length	Field Length	Cmd Desc.	Field Data	MSB	LSB
Command Poll AHRS Data	0x75	0x65	0x0C	0x02	0x02	0x01	Option: 0x00	ОхЕВ	0xDD
Reply ACK/NACK	0x75	0x65	0x0C	0x04	0x04	0xF1	Cmd echo: 0x11 Error code: 0x00	0xF0	0xCC
AHRS Data Packet field 1 (Gyro Vector)	0x75	0x65	0x80	0x1C	0x0E	0x04	0x3E 7A 63 A0 0xBB 8E 3B 29 0x7F E5 BF 7F		
AHRS Data Packet field 2(Accel Vector)					0x0E	0x03	0x3E 7A 63 A0 0xBB 8E 3B 29 0x7F E5 BF 7F	0xAD	0xDC

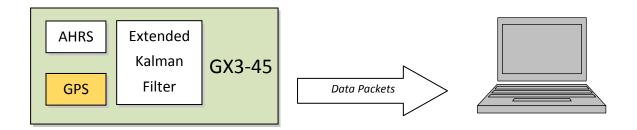

Copy-Paste version of the command: "7565 0C02 0201 00EB DD"

You may specify the format of the data packet on a per-polling-command basis rather than using the pre-set data format (see the <u>Poll AHRS Data</u> and <u>Poll NAV Data</u> sections)

The polling command has an option to suppress the ACK/NACK in order to keep the incoming stream clear of anything except data packets. Set the option byte to 0x01 for this feature.

Parsing Incoming Packets

Setup is usually the easy part of programming the 3DM-GX3-45. Once you start continuous data streaming, parsing and processing the incoming data packet stream will become the primary focus. The stream of data from the AHRS and Kalman Filter (NAV) are usually the dominant source of data since they come in the fastest. Polling for data may seem to be a logical solution to controlling the data flow, and this may be appropriate for some applications, but if your application requires the precise delivery of inertial data, it is often necessary to have the data stream drive the process rather than having the host try to control the data stream through polling.

The "descriptor set" qualifier in the MIP packet header is a feature that greatly aids the management of the incoming packet stream by making it easy to sort the packets into logical sub-streams and route those streams to appropriate handlers. The first step is to parse the incoming character stream into packets.

It is important to take an organized approach to parsing continuous data. The basic strategy is this: parse the incoming stream of characters for the packet starting sequence "ue" and then wait for the entire packet to come in based on the packet length byte which arrives after the "ue" and descriptor set byte. Make sure you have a timeout on your wait loop in case your stream is out of sync and the starting "ue" sequence winds up being a "ghost" sequence. If you timeout, restart the parsing with the first character after the ghost "ue". Once the stream is in sync, it is rare that you will hit a timeout unless you have an unreliable communications link. After verifying the checksum, examine the "descriptor set" field in the header of the packet. This tells you immediately how to handle the packet.

Based on the value of the descriptor set field in the packet header, pass the packet to either a command handler (if it is a Base command or 3DM command descriptor set) or a data handler (if it is a GPS, AHRS, or NAV data set). Since you know beforehand that the AHRS and NAV data packets will be coming in fastest, you can tune your code to buffer or handle these packets at a high priority. Likewise, you know that the GPS packets will be coming in at a much lower rate but may have much more data to process. Again, you can tune your code to buffer or handle these slower packets appropriately. Replies to commands generally happen sequentially after a command so the incidence of these is under program control.

For multithreaded applications, it is often useful to use queues to buffer packets bound for different packet handler threads. The depth of the queue can be tuned so that no packets are dropped while waiting for their associated threads to process the packets in the queue. See <u>Advanced Programming Models</u> section for more information on this topic.

Once you have sorted the different packets and sent them to the proper packet handler, the packet handler may parse the packet payload fields and handle each of the fields as appropriate for the application. For simple applications, it is perfectly acceptable to have a single handler for all packet types. Likewise, it is perfectly acceptable for a single parser to handle both the packet type and the fields in the packet. The ability to sort the packets by type is just an option that simplifies the implementation of more sophisticated applications.

MicroStrain supplies examples of parsers for "C", LabVIEW, and Visual Basic in the 3DM-GX3-45 SDK.

Multiple Rate Data

The message format commands (<u>AHRS Message Format</u>, <u>GPS Message Format</u>, and <u>NAV Message Format</u>) allow you to set different data rates for different data quantities. This is a very useful feature especially for AHRS data because some data, such as accelerometer and gyroscope data, usually requires higher data rates (100Hz) than other AHRS data such as Magnetometer (20Hz typical) data. The ability to send data at different rates reduces the parsing load on the user program and decreases the bandwidth requirements of the communications channel.

Multiple rate data is scheduled on a common sampling rate clock. This means that if there is more than one data rate scheduled, the schedules coincide periodically. For example, if you request Accelerometer data at 100Hz and Magnetometer data at 50Hz, the magnetometer schedule coincides with the Accelerometer schedule 50% of the time. When the schedules coincide, then the two data quantities are delivered in the same packet. In other words, in this example, you will receive data packets at 100Hz and every packet will have an accelerometer data field and EVERY OTHER packet will also include a magnetometer data field:

Packet 1	Packet 2	Packet 3	Packet 4	Packet 5	Packet 6	Packet 7	Packet 8	
Accel	Accel Mag	Accel	Accel Mag	Accel	Accel Mag	Accel	Accel Mag	Accel

If a timestamp is included at 100Hz, then the timestamp will also be included in every packet in this example. It is important to note that *the data in a packet with a timestamp is always synchronous with the timestamp.* This assures that multiple rate data is always synchronous.

Packet 1	Packet 2	Packet 3	Packet 4	Packet 5	Packet 6	
Accel Timestamp	Accel Mag Timestamp	Accel Timestamp	Accel Mag Timestamp	Accel Timestamp	Accel Mag Timestamp	Accel Timestamp

Data Synchronicity

Because the MIP packet allows multiple data fields to be in a single packet, it may be assumed that a single timestamp field in the packet applies to all the data in the packet. In other words, it may be assumed that all the data fields in the packet were sampled at the same time.

AHRS, GPS, and NAV data are generated independently by three systems with different clocks. The importance of time is different in each system and the data they produce. The AHRS data requires precise microsecond resolution and perfectly regular intervals in its timestamps. GPS data produces very precise UTC interval data but it is typically delivered in a 1 second time frame. The Kalman Filter resides on a separate processor and must derive its timing information from the two data sources.

The time base difference is one of the factors that necessitate separation of the GPS, AHRS, and NAV data into separate packets. Conversely, the common time base of the different data quantities within one system is what allows grouping multiple data quantities into a single packet with a common timestamp. In other words, AHRS data is always grouped with a timestamp generated from the AHRS time base, and GPS data is always grouped with a timestamp from the GPS time base, etc.

In many applications, synchronizing the timestamps from the three system time bases is critical. MicroStrain uses an extended timestamp across its product line to allow synchronization of data sampled on different system clocks. This timestamp relies on a pulse per second (PPS) beacon signal. On the 3DM-GX3-45, this PPS signal is generated by the on board GPS. The timestamp of the AHRS data represents the interval in nanoseconds from the last PPS pulse. This allows proper time alignment of the GPS data with the AHRS data. On other systems, the PPS signal is applied externally by a system wide PPS beacon. The 3DM-GX3-45 can be the source of this beacon by picking off the PPS output on the multi-com connector.

A second form of synchronization exists which can be slightly less accurate, but easier to use in practice. All data streams (AHRS, GPS, and NAV) on the GX3-45 output a "GPS Time"-formatted timestamp. This timestamp is synchronized between the 3 devices using the GPS 1PPS hardware beacon. Due to the differences in clocks on each device, the period between two consecutive timestamp values may not be constant; this occurs because periodic corrections are applied to the AHRS and NAV timestamps when the GPS 1PPS signal is asserted.

Communications Bandwidth Management

Because of the large amount and variety of data that is available from the 3DM-GX3-45, it is quite easy to overdrive the bandwidth of the communications channel. This can result in dropped packets. The 3DM-GX3-45 does not do any analysis of the bandwidth requirements for any given output data configuration, it will simply drop a packet if its internal serial buffer is being filled faster than it is being emptied. It is up to the programmer to analyze the size of the data packets requested and the available bandwidth of the communications channel. Often the best way to determine this is empirically by trying different settings and watching for dropped packets. Below are some guidelines on how to determine maximum bandwidth for your application.

UART Bandwidth Calculation

Below is an equation for the maximum theoretical UART BAUD rate for a given message configuration. Although it is possible to calculate the approximate bandwidth required for a given setup, there is no guarantee

that the system can support that setup due to internal processing delays. The best approach is to try a setting based on an initial estimate and watch for dropped packets. If there are dropped packets, increase the BAUD rate, reduce the data rate, or decrease the size or number of packets.

$$n(k \times f_{mr}) + n \sum (S_f \times f_{dr})$$

Where

 $S_f = Size \ of \ data \ field \ in \ bytes$ $f_{dr} = field \ data \ rate \ in \ Hz$ $f_{mr} = maximum \ data \ rate \ in \ Hz$ $n = size \ of \ UART \ word = 10bits$ $k = Size \ of \ MIP \ wrapper = 6 \ bytes$

which becomes

$$60f_{mr} + 10 \sum (S_f \times f_{dr})$$

Example:

For an AHRS message format of Accelerometer Vector (14 byte data field) + Internal Timestamp (6 byte data field), both at 100 Hz, the theoretical minimum BAUD rate would be:

$$= 60 \times 100 + 10((14 \times 100) + (6 \times 100))$$
$$= 26000 \text{ BAUD}$$

In practice, if you set the BAUD rate to 115200 the packets come through without any packet drops. If you set the BAUD rate to the next available lower rate of 19200, which is lower than the calculated minimum, you get regular packet drops. The only way to determine a packet drop is by observing a timestamp in sequential packets. The interval should not change from packet to packet. If it does change then packets were dropped.

USB vs. UART

The 3DM-GX3-45 has a dual communication interface: USB or UART. There is an important difference between USB and UART communication with regards to data bandwidth. The USB "virtual COM port" that the 3DM-GX3-45 implements runs at USB "full-speed" setting of 12Mbs (megabits per second). However, USB is a polled master-slave system and so the slave (3DM-GX3-45) can only communicate when polled by the master. This results in inconsistent data streaming – that is, the data comes in spurts rather than at a constant rate and although rare, sometimes data can be dropped if the host processor fails to poll the USB device in a timely manner.

With the UART the opposite is true. The 3DM-GX3-45 operates without UART handshaking which means it streams data out at a very consistent rate without stopping. Since the host processor has no handshake method of pausing the stream, it must instead make sure that it can process the incoming packet stream non-stop without dropping packets.

In practice, USB and UART communications behave similarly on a Windows based PC, however, UART is the preferred communications system if consistent, deterministic communications timing behavior is required. USB is preferred if you require more data than is possible over the UART and you can tolerate the possibility of variable latency in the data delivery and very occasional packet drops due to host system delays in servicing the USB port.

Command Reference

Base Commands

The Base command set is common to many MicroStrain devices. With the Base command set it is possible to identify many properties and do basic functions on a device even if you do not recognize its specialized functionality or data. The commands work the same way on all devices that implement this set.

3DM Commands

The 3DM command set is common to the MicroStrain Inertial sensors that support the MIP packet protocol. Because of the unified set of commands, it is easy to migrate code from one inertial sensor to another.

Poll AHRS Data (0x0C, 0x01)

		Doll the 2DNA CV2 AF for an AUDC recessor with the execitied former											
Description	Poll the	I the 3DM-GX3-45 for an AHRS message with the specified format											
Notes	maintain ignored. the Set A the device data pace	s function polls for an AHRS message using the provided format. The resulting message will intain the order of descriptors sent in the command and any unrecognized descriptors are bred. If the format is not provided, the device will attempt to use the stored format (set with Set AHRS Message Format command.) If no format is provided and there is no stored format, device will respond with a NACK. The reply packet contains an ACK/NACK field. The polled a packet is sent separately as an AHRS Data packet. Sible Option Selector Values: 0x00 - Normal ACK/NACK Reply. 0x01 - Suppress the ACK/NACK reply. Id Length Field Descriptor Field Data											
Field Format	Field Lei	ngth	Field Desc	riptor		Fiel	d Data						
Command	4 + 3*N		0x01			U8 – Option Selector U8 – Number of Descriptors (N), N*(U8 – Descriptor, U16 Reserved)							
Reply ACK/NACK	0x04		0xF1					ne command byte ode (0:ACK, not 0:NAC	CK)				
	MIP Packe	et Heade	r		Com	mand	l/Reply Fi	elds	Checksu	ım			
Examples	Sync1	Sync2	Desc Set	Payload Length	Field Leng		Field Desc.	Field Data	MSB	LSB			
Command Poll AHRS data (use stored format)	0х75	0x65	0x0C	0x04	4 0x04		0x01	Option: 0x00 Desc count: 0x00	OxEF	0xDA			
Command Poll AHRS data (use specified format)	0x75	0x65	0x0C	0x0A	0x0	A	0x01	Option: 0x00 Desc count: 0x02 1st Descriptor: 0x04 Reserved: 0x0000 2nd Descriptor: 0x05 Reserved: 0x0000	0x06	0x27			
Reply ACK/NACK (Data packet is sent separately if ACK)	0x75	0x65 0x0C 0x04 0x04 0xF1 Echo cmd: 0x01 0xE0 0xAC Error code: 0x00

AHRS Signal Conditioning Settings (0x0C, 0x35)

Description	Set, read, or save the AHRS signal conditioning parameters. This function sets the AHRS signal conditioning parameters for all communications and streaming modes. For all functions except 0x01 (use new settings), the new parameter values are ignored.
Notes	Possible function selector values: 0x01 – Apply new settings 0x02 – Read back current settings. 0x03 – Save current settings as startup settings 0x04 – Load saved startup settings 0x05 – Load factory default settings Possible Orientation Calculation Decimation values: 0x0002 to 0x03E8 (2 to 1000): This value divided into 1000 will determine the rate at which coning & sculling integration, and orientation calculations are made (including Matrix, Euler, and Quaternion). For example, a value of 10 results in 1000/10 = 100Hz calculation rate. Always overwritten to "0x000A" (10) on GX3-45. Possible Data Conditioning Flags: 0x0001 – Enables Orientation Calculation (Matrix/Euler). Always overwritten to "1" on GX3-45. 0x0002 – Enables Coning & Sculling. Default is "1". Always overwritten to "1" on GX3-45. 0x0040 – Enables finite size correction. Default is "0" 0x0400 – Disables Magnetometer. Default is "0" 0x0400 – Disables "North" compensation. Default is "0" 0x0800 – Disables "Up" compensation. Default is "0" 0x1000 – Enables Quaternion calculation. Always overwritten to "1" on GX3-45. Possible Gyro/Accel and Mag Filter Width values: 0x01 to 0x20 (1 to 32): This value divided into 1000 determines the bandwidth of the adjustable filter. See the section on "AHRS Filtering" for more information. Default is 15 for Accel/Gyro, 17 for Mag. Possible Up and North compensation values: 0x0001 to 0x03E8 (1 to 1000): This value represents how quickly (in seconds) the gravitational /magnetometer vectors correct the inertial attitude/yaw orientation results. Default is 10 (seconds) for both values.

	Possible	ossible Mag Power/Bandwidth values:										
		1: Ban	n bandwidt dwidth is c It is "1"	_	-	-	cion ower consumption.

Heading Update Control (0x0D, 0x18)

Description	Select t	elect the source for heading updates to the Kalman Filter.										
	Possible	e functio	n selector	· values:								
Notes	*The m World N heading **To us must ha When t defined defined	0x01 – Use new settings 0x02 – Read back current settings. 0x03 – Save current settings as startup settings 0x04 – Load saved startup settings 0x05 – Reset to factory default settings 0x05 – Reset to factory default settings Possible Enable Flag values: 0x00 – Disable Heading Updates 0x01 – Use the Magnetometer for Heading Updates* 0x02 – Use the Internal GPS Velocity Vector for Heading Updates** 0x03 – Use external heading updates *The magnetometer inclination angle (dip angle) is calculated and tested against the World Magnetic Model value. When an error of 30 degrees or more is detected, the heading is marked as invalid and is not used by the filter. **To use the Internal GPS velocity vector for heading updates, the target application must have no (or minimal) side-slip; this is true in most ground vehicle applications. When this option is selected, the sensor to vehicle frame transformation must be defined and match the physical mounting of the device. When no transformation is defined, the device must be mounted on the vehicle with the X-axis co-aligned with the direction of travel.

System Commands

The System Command set provides a set of advanced commands that are specific to devices such as the 3DM-GX3-35 that have multiple intelligent internal sensor blocks. These commands allow special mode such as talking directly to the native protocols of the embedded sensor blocks. For example, with the 3DM-GX3-35, you may switch into a mode that talks directly to the internal u-blox chip or directly to the embedded 3DM-GX3-25 AHRS. This allows you to use code or utilities written specifically for the native u-blox protocols (NMEA or UBX) and 3DM-GX3-25 protocols (original single byte commands or ASPP packet protocol).

			8	Z Accel	float	g		

Scaled Gyro Vector (0x80, 0x05)

Description	Scaled Gyro Vector						
Notes	This is a vector quantifying the rate of rotation (angular rate) of the 3DM-GX3®. This quantity is derived from the Raw Angular Rate quantities, but is fully temperature compensated and scaled into units of radians/second. It is expressed in terms of the 3DM-GX3®'s local coordinate system in units of radians/second.

	14 (0x0E)		4	Y Delta Theta	float	radians		
			8	Z Delta Theta	float	radians		

Delta Velocity Vector (0x80, 0x08)

Description	Time integral of	f velocity.				
Notes	This is a vector which gives the time integral of <i>Accel</i> where the limits of integration are the beginning and end of the most recent data rate period (eg., 0.01 seconds for a data rate of 100Hz). It is expressed in terms of the 3DM-GX3 [*] /s local coordinate system in units of g*second where g is the standard gravitational constant. To convert Delta Velocity into the more conventional units of m/sec, simply multiply by the standard gravitational constant, 9.80665 m/sec^2

	14 (0x0E)	0x0C	4	Pitch	float	radians
			8	Yaw	float	radians

GPS Correlation Timestamp (0x80, 0x12)

Description	GPS correlation timestamp.
Notes	This timestamp has three fields: Double GPS TOW U16 GPS Week number U16 Timestamp flags Timestamp Status Flags: Bit0 – PPS Beacon Good If set, GPS PPS signal is present Bit1 – GPS Time Refresh (toggles with each refresh) Bit2 – GPS Time Initialized (set with the first GPS Time Refresh) This timestamp correlates the AHRS packets with the GPS packets. It is identical to the GPS Time record except the flags are defined specifically for the AHRS. When the GPS Time Initialized flag is asserted, the GPS Time and AHRS GPS Timestamp are correlated. This flag is only set once upon the first valid GPS Time record. After that, each time the GPS Time becomes invalid (from a lack of signal) and then valid again (regains signal) the GPS Time Refresh flag will toggle. The GPS Time Initialized will remain set. The "PPS Beacon Good" flag in the Timestamp flags byte indicates if the PPS beacon coming from the GPS is present. If this flag is not asserted, it means that the AHRS internal clock is being used for the PPS. The fractional portion of the GPS TOW represents the amount of time that has elapsed from the last PPS.
	If the GPS loses signal, the GPS and AHRS timestamps become free running and will slowly drift

	away from each other. If the timestamp clocks have drifted apart, then there will be a jump in the timestamp when the PPS Beacon Good reasserts, reflecting the amount of drift of the clocks. See the Data Synchronicity section of this manual for more information on timestamps.

Heading Update Source State (0x82, 0x14)

Description	Heading Upda	te Source infor	mation expres	sed in the sens	or frame.					
	Heading updates can be applied from a number of sources (listed below.)									
	The heading value is always relative to true north.									
	Possible Sources:									
Notes	0x0000 – No source, heading updates disabled 0x0001 – Internal Magnetometer 0x0002 – Internal GPS Velocity Vector 0x0004 – External Heading Update Command Valid Flag Mapping: 0x0000 – No heading update received in 2 seconds. 0x0001 – The heading update source has provided data within 2 seconds.									
	Field Length	Data Descriptor		Messa	ge Data					
			Binary Offset	Description	Data Type	Units				
Field Format	12 (0x0C) 0x14		0	Heading (True)	Float	Radians				
		0x14	4	Heading 1- sigma	Float	Radians				
			8	Source	U16	See Notes				
			10	Valid Flags	U16	See Notes				

Magnetic Model Solution (0x82, 0x15)

Description	Magnetic model solution expressed in the NED frame.									
Notes	The World Magnetic Model 2010 is used. A valid GPS location is required for the model to be valid. Valid Flag Mapping: 0x0000 – Magnetic model solution is invalid (note: this will be the state when the magnetic model is recalculating for the current time and location as well as when GPS is unavailable) 0x0001 – Magnetic model solution is valid									
	Field Length	Data Descriptor	Message Data							
			Binary Offset	Description	Data Type	Units				
			0 Intensity (North)	•	Float	Gauss

			16	Declination Float		Radians				
			20	Valid Flags	U16	See Notes				

MIP Packet Reference

Structure

Commands and Data are sent and received as fields in the MicroStrain "MIP" packet format. Below is the general definition of the structure:

Header			Payload	Payload				
SYNC1 "u"	SYNC2 "e"	Descriptor Set byte	Payload Length byte	Fields	Fields			LSB
0x75	0x65	<desc selector="" set=""></desc>	$k_1+k_2+k_n$	MIP Field 1 length = k_1		MIP Field n length = k_n	0xMM	0x <i>LL</i>
		_						<u></u>
	Field Header				Field Data			
9 ,			Field Descriptor byte	Field Data				
			k _n	<descriptor></descriptor>	descriptor> $\langle k_n-2 \rangle$ bytes of data>			

The packet always begins with the start-of-packet sequence "ue" (0x75, 0x65). The "Descriptor Set" byte in the header specifies which command or data set is contained in fields of the packet. The payload length byte specifies the sum of all the field length bytes in the payload section.

Payload Length Range

Packet Header			Payload	Checksum		
SYNC 1	SYNC 2	Descript or Set	Payload Length	MIP Data Fields	MSB	LSB
				<payload length="" range=""></payload>		

The payload section can be empty or can contain one or more fields. Each field has a length byte and a descriptor byte. The field length byte specifies the length of the entire field including the field length byte and field descriptor byte. The descriptor byte specifies the command or data that is contained in the field data. The descriptor can only be from the set of descriptors specified by the descriptor set byte in the header. The field data can be anything but is always rigidly defined. The definition of a descriptor is fundamentally described in a ".h" file that corresponds to the descriptor set that the descriptor belongs to.

MicroStrain provides a "MIP Packet Builder" utility to simplify the construction of a MIP packet. Most commands will have a single field in the packet, but multiple field packets are possible. Extensive examples complete with checksums are given in the command reference section.

Checksum Range

The checksum is a 2 byte Fletcher checksum and encompasses all the bytes in the packet:

Packet Header				Payload	Checksum		
SYNC 1	SYNC 2	Descrip tor Set	Payload Length	MIP Data Fields	MSB (byte1)	LSB (byte2)	
<	<>						

16-bit Fletcher Checksum Algorithm (Clanguage)

```
for(i=0; i<checksum_range; i++)
{
  checksum_byte1 += mip_packet[i];
  checksum_byte2 += checksum_byte1;
}
checksum = ((u16) checksum_byte1 << 8) + (u16) checksum_byte2;</pre>
```

Advanced Programming

Multiple Commands in a Single Packet

MIP packets may contain one or more individual commands. In the case that multiple commands are transmitted in a single MIP packet, the GX3-45 will respond with a single packet containing multiple replies. As with any packet, all commands must be from the same descriptor set (you cannot mix Base commands with 3DM commands in the same packet).

Below is an example that shows how you can combine the commands from step 2 and 3 of the <u>Example Setup Sequence</u> into a single packet. The commands are from the 3DM set. The command packet has two fields as does the reply packet (the fields are put on separate rows for clarity):

Step 2 and 3	MIP Packe	et Header			Comman	d/Reply Fie	elds	Checksum	
	Sync1	Sync2	Desc Set	Payload Length	Field Length	Cmd Desc.	Field Data	MSB	LSB
Command field 1 Set AHRS Message Format	0x75	0x65	0x0C	0x14	0x0A	0x08	Function: 0x00 Desc count: 0x02 1st Descriptor: 0x03 Rate Dec: 0x000A 2nd Descriptor: 0x04 Rate Dec: 0x000A		
Command field 2 Set GPS Message Format					0x0A	0х09	Function: 0x00 Desc Count: 0x02 ECEF pos desc: 0x04 Rate dec: 0x0004 ECEF vel desc: 0x06 Rate dec: 0x0004	0x50	0x98
Reply field 1 ACK/NACK	0x75	0x65	0x0C	0x08	0x04	0xF1	Cmd echo: 0x08 Error code: 0x00		
Reply field 2 ACK/NACK					0x04	0xF1	Cmd echo: 0x09 Error code: 0x00	0xE9	0x6F

Copy-Paste version of the command: "7565 0C14 0A08 0002 0300 0A04 000A 0A09 0002 0400 0406 0004 5098"

Note that the only difference in the packet headers of the single command packets compared to the multiple command packets is the payload length. Parsing multiple fields in a single packet involves subtracting the field length of the next field from the payload length until the payload length is less than or equal to zero.

Direct Modes

The GX3-45 has special "direct" modes that switch the device into a "GX3-25" AHRS or a "u-blox" GPS device. The <u>Device Communications Mode</u> command is used to switch between modes. When in these modes, the GX3-45 acts just like a GX3-25 AHRS or a u-blox GPS sensor respectively. Any code or tools developed for these devices may be used in these modes. For example, when in the "u-blox" direct mode, the u-blox "u-center" application works perfectly with the GPS chip embedded in the GX3-45.

These modes can be used to change advanced settings of the individual sensors, settings that aren't represented in the 3DM command sets of the GX3-45.

IMPORTANT: When you switch modes, you are switching to a new device protocol EXCEPT for two commands: the <u>Device Communications Mode</u> and <u>Device Status</u> commands. Those commands are always available regardless of which mode you are in. For example, if you switch to GPS direct mode, then the protocol recognized by the device is NMEA and UBX protocol, however the GX3-45 is still "listening" for mode switch or device status commands and will respond to them. It will not respond to any other 3DM-GX3-45 Basic or 3DM commands until switched back to the "Standard Mode".

IMPORTANT: The GPS message settings required for Kalman Filter execution are automatically reloaded when switching from direct modes back in to standard mode.

Internal Diagnostic Functions

The 3DM-GX3-45 supports two device specific internal functions used for diagnostics and system status. These are <u>Device Built In Test</u> and <u>Device Status</u>. These commands are defined generically but the implementation is very specific to the hardware implemented on this device. Other MicroStrain devices will have their own implementations of these functions depending on the internal hardware of the devices.

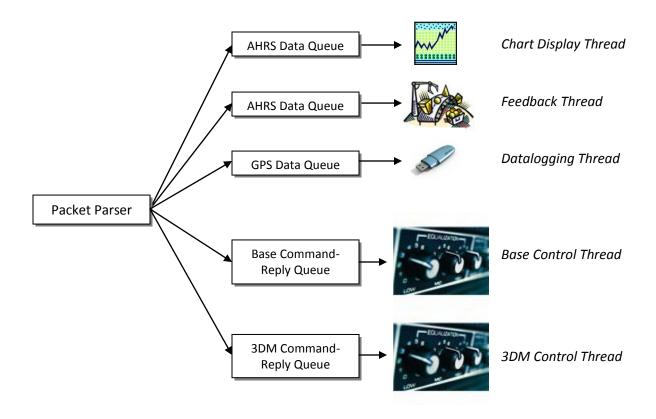

3DM-GX3-45 INTERNAL DIAGNOSTIC COMMANDS

<u>Device Built In Test</u> (0x01, 0x05)
 Device Status (0x0C, 0x64)

Advanced Programming Models

Many applications will only require a single threaded programming model which is simple to implement using a single program loop that services incoming packets. In other applications, advanced techniques such as multithreading or event based processes are required. The MIP packet design simplifies implementation of these models. It does this by limiting the packet size to a maximum of 261 bytes and it provides the "descriptor set" byte in the header. The limited packet size makes scalable packet buffers possible even with limited memory space. The descriptor set byte aids in sorting an incoming packet stream into one or more command-reply packet queues and/or data packet queues. A typical multithreaded environment will have a command/control thread and one or more data processing threads. Each of these threads can be fed with individual incoming packet queues, each containing packets that only pertain to that thread – sorted by descriptor set. Packet queues can easily be created dynamically as threads are created and destroyed. All

packet queues can be fed by a single incoming packet parser that runs continuously independent of the queues. The packet queues are individually scaled as appropriate to the process; smaller queues for lower latency and larger queues for more efficient batch processing of packets.

Multithreaded application with multiple incoming packet queues
